

Java Notes - Methods in Java (One Page)

What is a Method?

A **method** is a block of code that performs a specific task. It helps reuse code, belongs to a class, defines behavior, and executes only when called.

Example

```
public static void playMusic() { ... }  
public static void buy(int cost) { ... }
```

Method Calls:

```
playMusic();  
buy(cost);
```

Parts of a Method

public - Access modifier
static - Belongs to the class
void - No return value
buy - Method name
int cost - Parameter

Return Types

void - No return value
int - Returns an integer
String - Returns text
boolean - Returns true or false

Parameters

Parameters receive values passed to a method. Example: **buy(15);**

Main Method

```
public static void main(String[] args)  
Execution starts from the main() method.
```

Advantages

Code reusability, Less duplication, Better readability, Easier debugging, Modular programming.

Quick Revision

Method = Task | Parameter = Input | void = No return | main() = Program starts
